orchid

Alternate titles: Orchidaceae

Introduction

E.R. Degginger

Orchid, (family Orchidaceae), any of nearly 1,000 genera and more than 22,000 species of attractively flowered plants distributed throughout the world, especially in wet tropics. Orchidaceae is a member of Asparagales, an order of monocotyledonous flowering plants that also includes the asparagus and iris families. The word *orchid* is derived from the Greek word (*orchis*) for testicle because of the shape of the root tubers in some species of the genus *Orchis*. These nonwoody perennial plants are generally terrestrial or epiphytic herbs (i.e., growing on other plants rather than rooted in soil). Those attached to other plants often are vinelike and have a spongy root covering called the velamen that absorbs water from the surrounding air. Most species manufacture their own food, but some live on dead organic material (saprophytic) or are helped to obtain nourishment by a fungus living in their roots.

Structural diversity

Contunico © ZDF Enterprises GmbH, Mainz

As a group, the orchids are different from other plants but only in the morphological (structural) characteristics associated with the flower and its organization. Even the special characteristics of orchid flowers, such as the masses of pollen called pollinia, the joining of the stamens and pistil to form a column, and the tiny seeds without endosperm are found individually in other groups of flowering plants. It is through the combination of several characteristics that a family of flowering plants, the Orchidaceae, emerges.

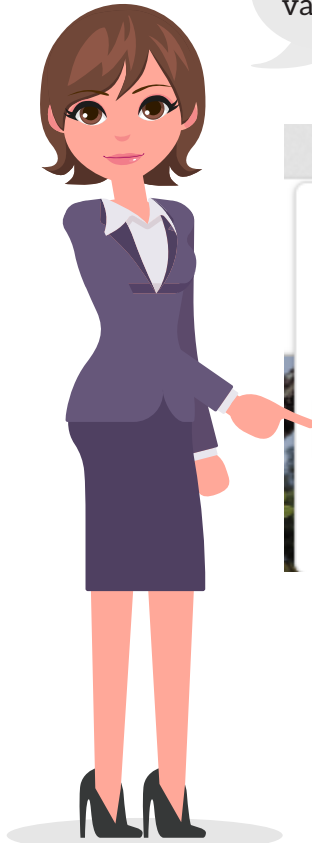

Orchids are primarily herbaceous (nonwoody), although some species may be vines, vinelike, or somewhat shrubby. They may be terrestrial or epiphytic. Orchid flowers vary tremendously in size from the minute flowers of some species of the genus *Pleurothallis*, which are no more than about 2 millimetres (0.1 inch) in diameter, to the large ones of *Brassia*, which may be more than 38 centimetres (15 inches) from the tips of the lateral sepals (petallike structures) to the tip of the dorsal sepal. The wide range of growth habits varies from those in which the plant is reduced to no more than roots (*Dendrophylax*), to saprophytic plants apparently lacking chlorophyll (*Coralorhiza*), to gigantic plants (*Arundina*) that superficially resemble a bamboo. Further, the diversity of structure among orchid flowers can be attributed mainly to the methods of pollination found in the family or to the fact that the family is adapted for the utilization of a number of different types of pollinators.
